01 Summary

During the third and fourth weeks of July, 1980, as requested by the Central Region of the Ministry of the Environment, the Monitoring and Instrumentation Development Unit of the Air Resources Branch conducted an ambient air survey in Toronto in the Junction Triangle area. The main purpose of this survey was to assess the peak concentrations of specific hydrocarbons in the vicinity of Glidden Paint Company Ltd, Anchor Cap and Closure Corporation of Canada Ltd, National Starches Nacan Products Ltd and the Junction Triangle area as a whole.

Very warm, humid and unstable air pushed northward from the south central United States into Ontario during this survey. Showers and thunderstorm activity were common; however, considerable low-level atmospheric stability was established through nocturnal cooling.

Ground level concentration (glc) data for ozone (O_3) and total hydrocarbons (THC) were acquired on a continuous basis by the Mobile Air Monitoring (MAM) Unit and 166 instantaneous ambient air samples were acquired and subsequently analyzed for a variety of hydrocarbons by a gas chromatograph contained in the MAM unit during this survey.

From the 37 monitoring periods comprising this survey, approximately 54 hours of continuously monitored THC data were acquired. Significant glc's of THC were recorded. The overall average THC glc was 4.10 ppm (parts per million) with associated standard deviation 1.20 ppm. The non-methane components were the more dominant species with their overall average glc being 2.64 ppm and associated standard deviation 1.02 ppm. The methane component overall average glc was 1.12 ppm.

The largest maximum one-hour average glc of THC was 7.47 ppm and was detected in the vicinity of Glidden Paint Co. Ltd. The largest maximum one-hour average THC glc detected in the vicinity of Anchor Cap was 6.95 ppm.

Low glc's of ozone (O_3) were detected during this survey. From the 54 hours of acquired data, the overall average glc for O_3 was 0.025 ppm with associated standard deviation 0.013 ppm. At no time was the desirable Ambient Air Quality Criterion for ozone (i.e. 0.08 ppm) exceeded during this survey.

Analyses of ambient air samples for peak concentrations of specific hydrocarbons were requested by the Ministry of Labour. These analyses were performed by a gas chromatograph (GC). It must be stressed that these readings cannot be directly compared to the established Ambient Air Quality Criteria or Guidelines, which are based on specific time intervals (usually 1 hour, 8 hour or 24 hour), during which period the concentrations of the components of the ambient air sample must be continuously integrated/averaged. However in the absence of any other concentration reference or benchmark, the respective Criterion or Guideline will be mentioned in the discussion of the specific hydrocarbons.

The field procedure dictated that the sampling for the specific hydrocarbons by the GC would take place only when the continuous monitoring THC instrument showed a peak HC response/concentration. Therefore all the GC results are biased towards the high concentrations. For example, if the average concentration of the instantaneous analyses taken over the appropriate time interval (for example; the average of 5 readings taken over 1 hour duration) is equal or less than the respective Criterion or Guideline, then the average concentration taken on a continuous basis would be with all probability less than that Criterion or Guideline. This is the only comparison that can be made with respect to the Ambient Air Quality.

Sixty-six ambient air samples were acquired in the vicinity of Glidden Paint. From the subsequent analyses, the geometric mean glc of 1,2,4-trimethyl benzene was 40 ug/m^3 with the maximum being 231 ug/m^3 . Seven of the 66 samples resulted in 1,2,4-trimethyl benzene glc's in excess of 100 ug/m^3 . Similarly the geometric mean glc of 1,3,5-trimethyl benzene was 11 ug/m^3 with the maximum being 109 ug/m^3 . Only one of the 66 samples depicted 1,3,5-trimethyl benzene glc's in excess of 100 ug/m^3 . Other significant maxima and mean glc's were; total xylenes- 1700 ug/m^3 and 196 ug/m^3 ; ethyl benzene - 374 ug/m^3 and 35 ug/m^3 ; toluene- 992 ug/m^3 and 150 ug/m^3 ; methyl ethyl ketone (MEK)- 513 ug/m^3 and 51 ug/m^3 . The maxima glc's of decane and isophorone were 480 ug/m^3 and 676 ug/m^3 respectively. (Only 3 or 4 samples were analyzed for these latter two hydrocarbons.)

Contaminants resulting from the combined emissions of many sources evolve into a uniform atmospheric loading and the geometric standard deviation of the acquired glc data usually lies in the range 1.85 to 2.4. For a single emission source, the geometric standard deviation would be higher. Thus the geometric standard deviation for xylenes (2.8), ethyl benzene (2.8), toluene (2.5), MEK (2.6) and the trimethyl benzenes (2.5) imply a discrete source in this area. In addition, the correlation analyses between the glc's of toluene and m/p xylene (significant at the 95% confidence level) also implies a mutual source for these two contaminants.

Sixty-three ambient air samples were acquired in the vicinity of Anchor Cap and Closure Corporation of Canada Ltd. From the subsequent G.C. analyses, the geometric mean glc of 1,2,4-trimethylbenzene was 81 ug/m^3 with the maximum being 516 ug/m^3 . Twenty-one of the 63 ambient air samples contained glc's of 1,2,4-trimethyl benzene in excess of 100 ug/m^3 . Similarly the geometric mean glc of 1,3,5-trimethyl benzene was 18 ug/m^3 with a maximum 207 ug/m^3 . Three of the 63 samples depicted 1,3,5-trimethyl benzene glc's in excess of 100 ug/m^3 . Other significant maxima and geometric mean glc's detected in these 63 samples were; total xylenes - 384 ug/m^3 and 69 ug/m^3 ; ethyl benzene - 71 ug/m^3 and 12 ug/m^3 ; methyl ethyl ketone - 86 ug/m^3 and 36 ug/m^3 ; toluene - 174 ug/m^3

and 36 ug/m^3 and methyl butyl ketone- 289 ug/m^3 and 9 ug/m^3 . Correlation analyses between the trimethyl benzenes and methyl butyl ketone suggested a mutual origin; all statistics being significant at the 99.9% confidence level. Similarly the geometric standard deviation for 1,2,4-trimethyl benzene (2.5), 1,3,5-trimethyl benzene (4) and methyl butyl ketone (3) implied a discrete source in this area.

In general, lower glc's of the aforementioned specific hydrocarbons were detected in the vicinity and directly downwind of National Starches - Nacan Ltd. From the subsequent analyses of the 16 ambient air samples, the more significant maxima and geometric mean glc's were; 1,2,4-trimethyl benzene - 53 ug/m^3 and 22 ug/m^3 ; 1,3,5-trimethyl benzene- 33 ug/m^3 and 6 ug/m^3 ; toluene- 225 ug/m^3 and 82 ug/m^3 ; methyl ethyl ketone- 738 ug/m^3 and 42 ug/m^3 and total xylenes - 180 ug/m^3 and 47 ug/m^3 . The toluene and methyl ethyl ketone glc's were the highest recorded during this entire survey.

During the last two days of this survey, the mobile air monitoring unit was positioned at several locations throughout the Junction Triangle area in order to assess the overall ambient air quality.

Low glc's of the aforementioned hydrocarbons were detected from the 21 ambient air samples comprising this segment of the survey. The following maximas and geometric mean glc's were monitored; 1,2,4-trimethyl benzene- 41 ug/m^3 and 17 ug/m^3 ; 1,3,5-trimethyl benzene- 16 ug/m^3 and 5 ug/m^3 ; xylenes- 145 ug/m^3 and 41 ug/m^3 and toluene - 153 ug/m^3 and 42 ug/m^3 .

From the aforementioned 166 ambient air samples analyzed by the gas chromatograph, benzene glc's were found to be essentially uniform throughout the

Junction Triangle area. The maximum benzene glc detected in the vicinity of Glidden Paint Company Ltd. was 70 ug/m^3 ; Anchor Cap and Closure Corporation of Canada Ltd. was 60 ug/m^3 ; National Starches-Nacan Ltd. was 85 ug/m^3 and the general ambient air survey was 92 ug/m^3 . The mobile air monitoring van was located directly downwind of a gas station when the 92 ug/m^3 of benzene were detected.

02. Introduction

As requested by the Central Region, the Monitoring and Instrumentation Development Unit of the Air Resources Branch conducted an ambient air survey in the "Junction Triangle" area of Toronto during the period of July 17 to August 1, 1980. The Junction Triangle is located in the west central part of Toronto and is bounded by Bloor St. on the south, Dundas St. on the west, Dupont on the north and Lansdowne Ave. on the east.

The main purpose of this ambient air survey was to provide peak readings on specific hydrocarbons, as ^{selected}~~determined~~ by the Ministry of Labour, in the vicinity of Anchor Cap and Closure Corporation of Canada Ltd., National Starches - Nacan Products Ltd. and the Glidden Paint Company.

03. Source Description

The area under investigation during this survey was the "Junction Triangle" in Toronto, with emphasis on the Anchor Cap and Closure Corporation of Canada Ltd., National Starches - Nacan Products Ltd., and the Glidden Paint Company.

Anchor Cap produces synthetic plastic materials with chemical processes using various resins and solvents. A large number of different hydrocarbons have been identified in the emissions from the lacquer, plastisol and lithograph ovens among the several emission points on the Anchor Cap property.

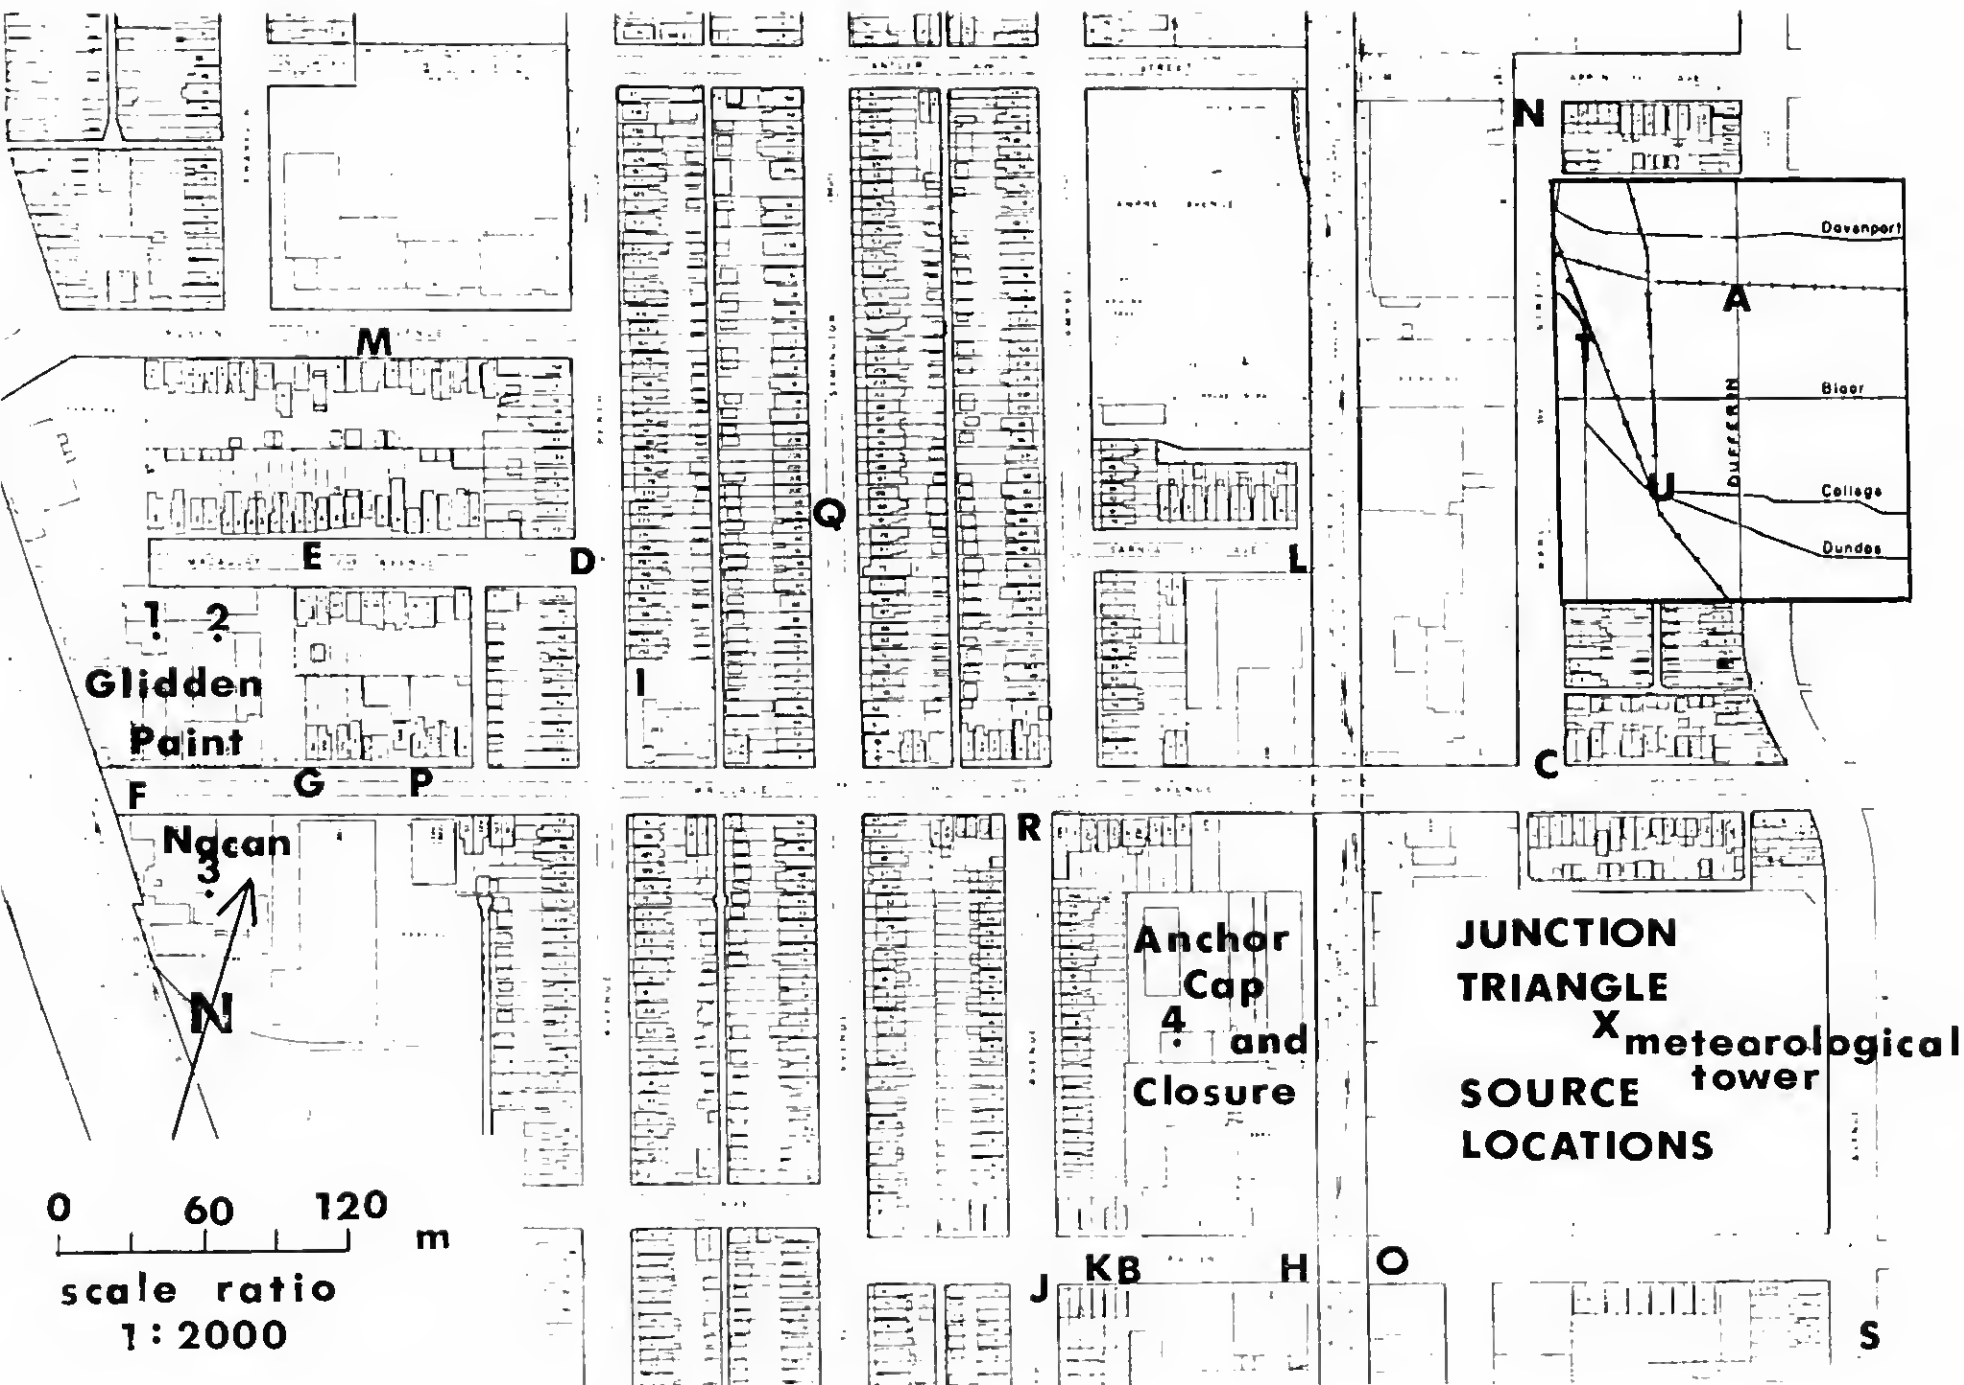

Nacan produces several glues, resins and solvents, and many different hydrocarbons have been identified from the emission points on the Nacan process buildings as well.

Glidden produces several paints, lacquers, varnishes and adhesives; again, several hydrocarbons have been identified from the emission points on the Glidden buildings. In addition, a tank farm on the Glidden property is a suspected source of several hydrocarbons.

The locations of these companies and their respective emission points are shown on Map #1, on page 10. The location of the meteorological tower used during the survey period is also included for the reader's convenience.

In addition, several photographs of the actual survey are presented.

04. Survey Technique

Analytical instrumentation housed in a 1975 General Motors Corporation "Transmode" was utilized to monitor the requested contaminants in the "Junction Triangle" area in Toronto. This mobile air monitoring (MAM) unit was equipped with an automated data acquisition system (Hewlett Packard 9830A mini-computer) and on-board electric generators for fully automated, independent and continuous monitoring capabilities. The HP 9830A mini-computer performed initial data analyses in the field (re: accuracy & validity) whereas the final data reduction and analyses were carried out by a larger computer system located within the Air Resources Branch at 880 Bay Street, Toronto.

The MAM unit has permanently installed analyzers for monitoring sulphur dioxide, hydrogen sulphide, carbon monoxide, ozone, oxides of nitrogen, total hydrocarbons and methane; however, only the total hydrocarbons and ozone analyzers were operational continuously throughout the survey. Meteorological instrumentation for monitoring wind speed, wind direction, relative humidity, temperature, barometric pressure, and solar radiation and vertical wind/temperature profiles were also included in this instrumentation package. In addition, as requested by the Region, a gas chromatograph (GC) unit was set up for a more complete hydrocarbon analyses. See Table #1 on page 16, for a listing of the above instrumentation.

Following an assessment of wind direction and wind speed, suitable ambient air monitoring sites were chosen. Air quality was continuously monitored for at least 1½ hours at each site.

05. Monitoring Technique

Sample Collection

The ambient air samples were taken at a constant flow rate of approximately $0.2 \text{ m}^3/\text{min}$. by a probe located on top of the MAM unit whose orifice was located approximately 5 metres above ground level. Air samples entered a manifold from which each analyzer including the GC was parallel tapped with a minimal length of teflon sampling line. This arrangement ensured little or no sample degradation due to ground level sources (e.g. entrained soil, vehicular traffic, etc.).

Instrumentation - Analyzers

The instruments associated with the MAM unit are presented in Table #1 on page 16.

Instrumentation - GC and Hydrocarbon Sample Collection Methods

The analysis of hydrocarbons in ambient air was performed by a Hewlett-Packard Gas Chromatograph (HP 5840A) and a microprocessing unit (HP 18850A GC terminal). Operating parameters were monitored automatically by the microprocessing unit once the programme was entered.

G.C. Operating Conditions

column - capillary, fused silica 0.3 mm I.D., 50m long, carbowox 20M
deactivated, coated with SP-1200

carrier gas - Helium, 4 ml/min (linear velocity 95cm/sec)

make-up gas - Nitrogen, 8ml/min

detector - Photoionization, 10.2 eV lamp, 150°C

sample volume - 5 ml sampling loop

temperature programming - 30°C-hold for 2 min, 30°C/min for 2 min,
20°C/min up to 170°C, hold for 2 min.

Ambient air hydrocarbon samples were extracted by the sampling loop and analyzed by the GC for the following hydrocarbons: methyl ethyl ketone (MEK), benzene, ethyl acrylate, methyl methacrylate, methyl butyl ketone (MBK), toluene, n-octane, ethyl benzene, m-xylene, cyclohexanone, o-xylene, nonane, iso propyl benzene, n-propyl benzene, 1,3,5-trimethyl benzene, 1,2,4-trimethyl benzene, decane, and isophorone.

The G.C. was calibrated by a sample of air with a known concentration of the above hydrocarbons.

Photoionization Detection (PID)

In addition to the THC analyzer associated with the MAM unit, qualitative assessment of the ambient air for THC was performed by a portable HNu photoionization detector. This detector was carried in a support van and was only used to locate HC plumes and to assess the status of several odour complaint episodes. If a significant concentration of HC was present during a complaint episode, the MAM unit would be called in for a more detailed investigation. However this latter procedure was not carried out due to

very low HC concentrations recorded by the PID analyzer during these complaint episodes.

Meteorological Analysis

Meteorological conditions were monitored on a continuous basis by the instrumentation in the MAM unit (refer to Table #1, page 16).

Calibration

Analyzers and sources were calibrated before the survey. During the survey, the calibration of the analyzers was checked at least once every day using calibrated sources and built in electronic circuitry. All monitors were found to be stable and calibration remained within the prescribed limits throughout the duration of the survey. Immediately following completion of the survey, all instruments were rechecked in the laboratory and all calibration statistics were found to be satisfactory.

07. RESULTS

Definition of Terms

Scan Time:	Frequency of interrogation of the monitoring instrumentation by the data acquisition system.
Time:	Time of the first and final scans used to determine running averages.
Number of Readings:	Number of scans
MAM:	Mobile Air Monitoring
glc:	ground level concentration

With respect to the continuous ambient air monitoring instrumentation associated with the MAM unit, all statistical values are based on cumulative averages of continuous instantaneous interrogations of the monitoring instruments and all results are expressed in parts per million (ppm). Due to the large quantity of this data, time averages will be included in the addendum entitled "Ambient Air Survey in the "Junction Triangle" Area - Toronto, July - August, 1980, compilation of Time Averaged Data", which will accompany this report and will be available upon request. Both 30 and 60 minute averages of the data will be presented in this addendum.

The statistical summary of the collected data is presented in Tables #10 to #13, pages 59 to 68. Supplementing these tables, concentration versus time graphs are presented in Figures # 1 to #7, pages 52 to 58.

In order to assist in source identification, wind rose/concentration analyses were also carried out (see Maps #3 and #4, pages 37 and 42).

08. Discussion

During the third week of July, a persistent high pressure ridge over the central United States slowly moved northeastward resulting in a west to southwesterly flow over Ontario. The approach of this high pressure ridge brought warm, humid air from the southern States into Ontario. The atmosphere was unstable and consequently, shower and thunderstorm activity was common.

During the last week of July, the weather was dominated by a broad trough behind this ridge. A very warm, humid and unstable air mass just south of the United States border began to push northward triggering thunderstorm activity on several occasions.

Despite generally unstable atmospheric conditions, considerable low-level stability was established through nocturnal cooling.

A meteorological station was established at the Toronto Transit Commission garage on Paton Road and Lansdowne Avenue and was run continuously from July 14 to August 4. The wind frequency rose analyses (Rose #1 on page 29) clearly donates that the wind was predominantly from the NW and S directions (25% and 22% respectively) throughout this survey period.

With respect to wind dynamics in this area, the major railway lines running N/S adjacent to Anchor Cap and Glidden/Nacan induced slight channeling especially during windy conditions. In general, the urban environment of the Junction Triangle area induced only slight orographic modification and all monitoring was performed when wind velocities were less than 20 km/hr.

As mentioned in Section 04, Survey Technique, only the glc data for ozone and total hydrocarbons acquired on a continuous basis (for total of 66 hours) and the 166 instantaneous samples acquired by the gas chromatograph will be discussed in the ensuing discussion. The ozone and total hydrocarbon data will be treated as air quality data for the entire Junction Triangle area with averaged glc's based on 60 minutes whereas the instantaneous G.C. data will be discussed with reference to a particular suspected source.

It must be pointed out that during the 66 hours of ambient air monitoring, the MAM Unit essentially monitored worse-case conditions. As stipulated in the Ontario Environmental Protection Act, impingement zone monitoring was undertaken whenever and wherever feasible and upon locating these zones (by spatial/temporal scan with the analytical instruments, analyzing the prevailing wind/dynamics of the area, and by visual and olfactory discriminatory techniques), ambient air monitoring was conducted for a period of 1½ hours so as to ensure a true, representative 60-min average glc of the continuously monitored gaseous contaminant(s) was obtained.

Qualitative measurements for hydrocarbons by the Portable Photo-ionization detector (see section 05) also assisted in the determination of these impingement zones for high hydrocarbon glc's.

As will be noted in the statistical summary tables for O₃ and THC, the glcs' arithmetic mean and standard deviation are given. Since monitoring was undertaken for a period of at least 1½ hours during each one of the monitoring periods (MP), if the arithmetic mean depicted a glc in excess of the Criterion, then the Criterion must have been exceeded during the monitoring period.

These results do not truly relate the status of the air quality in this area since the monitor was not permanently placed but rather reflect the success of impingement zone monitoring.

Geometric analyses were applied to the specific, instantaneous hydrocarbon contaminants as analyzed by the G.C. Since it was assumed that these specific hydrocarbons were lognormally distributed, the geometric standard deviation would also lend some insight into source(s) delineations. If the geometric standard deviation was greater than 2, a discrete source was implied for that contaminant.

The instantaneous ambient air samples analyzed by the gas chromatograph were acquired only when the total hydrocarbon analyzer depicted a maxima. Thus these results were not randomly acquired (with respect to time or expected concentration) and would reflect maximum loadings in the Junction Triangle area.

Because of this biasing, if the average concentration of the instantaneous analyses taken over the appropriate time interval (for example; the average of 5 readings taken over 1 hour) was equal or less than the respective Criterion or Guideline, then the average concentration of that particular contaminant taken on a continuous basis would also be with all probability less than the respective Criterion or Guideline. Criterion and Guidelines require definite time intervals.

Since this is the only comparison that can be made between the instantaneous and continuous frames of reference in the discussion of the GC analyses and ambient air quality, the 30-min. Guidelines for the specific hydrocarbons will be referred to for comparisons only and will be stated as "benchmarks".

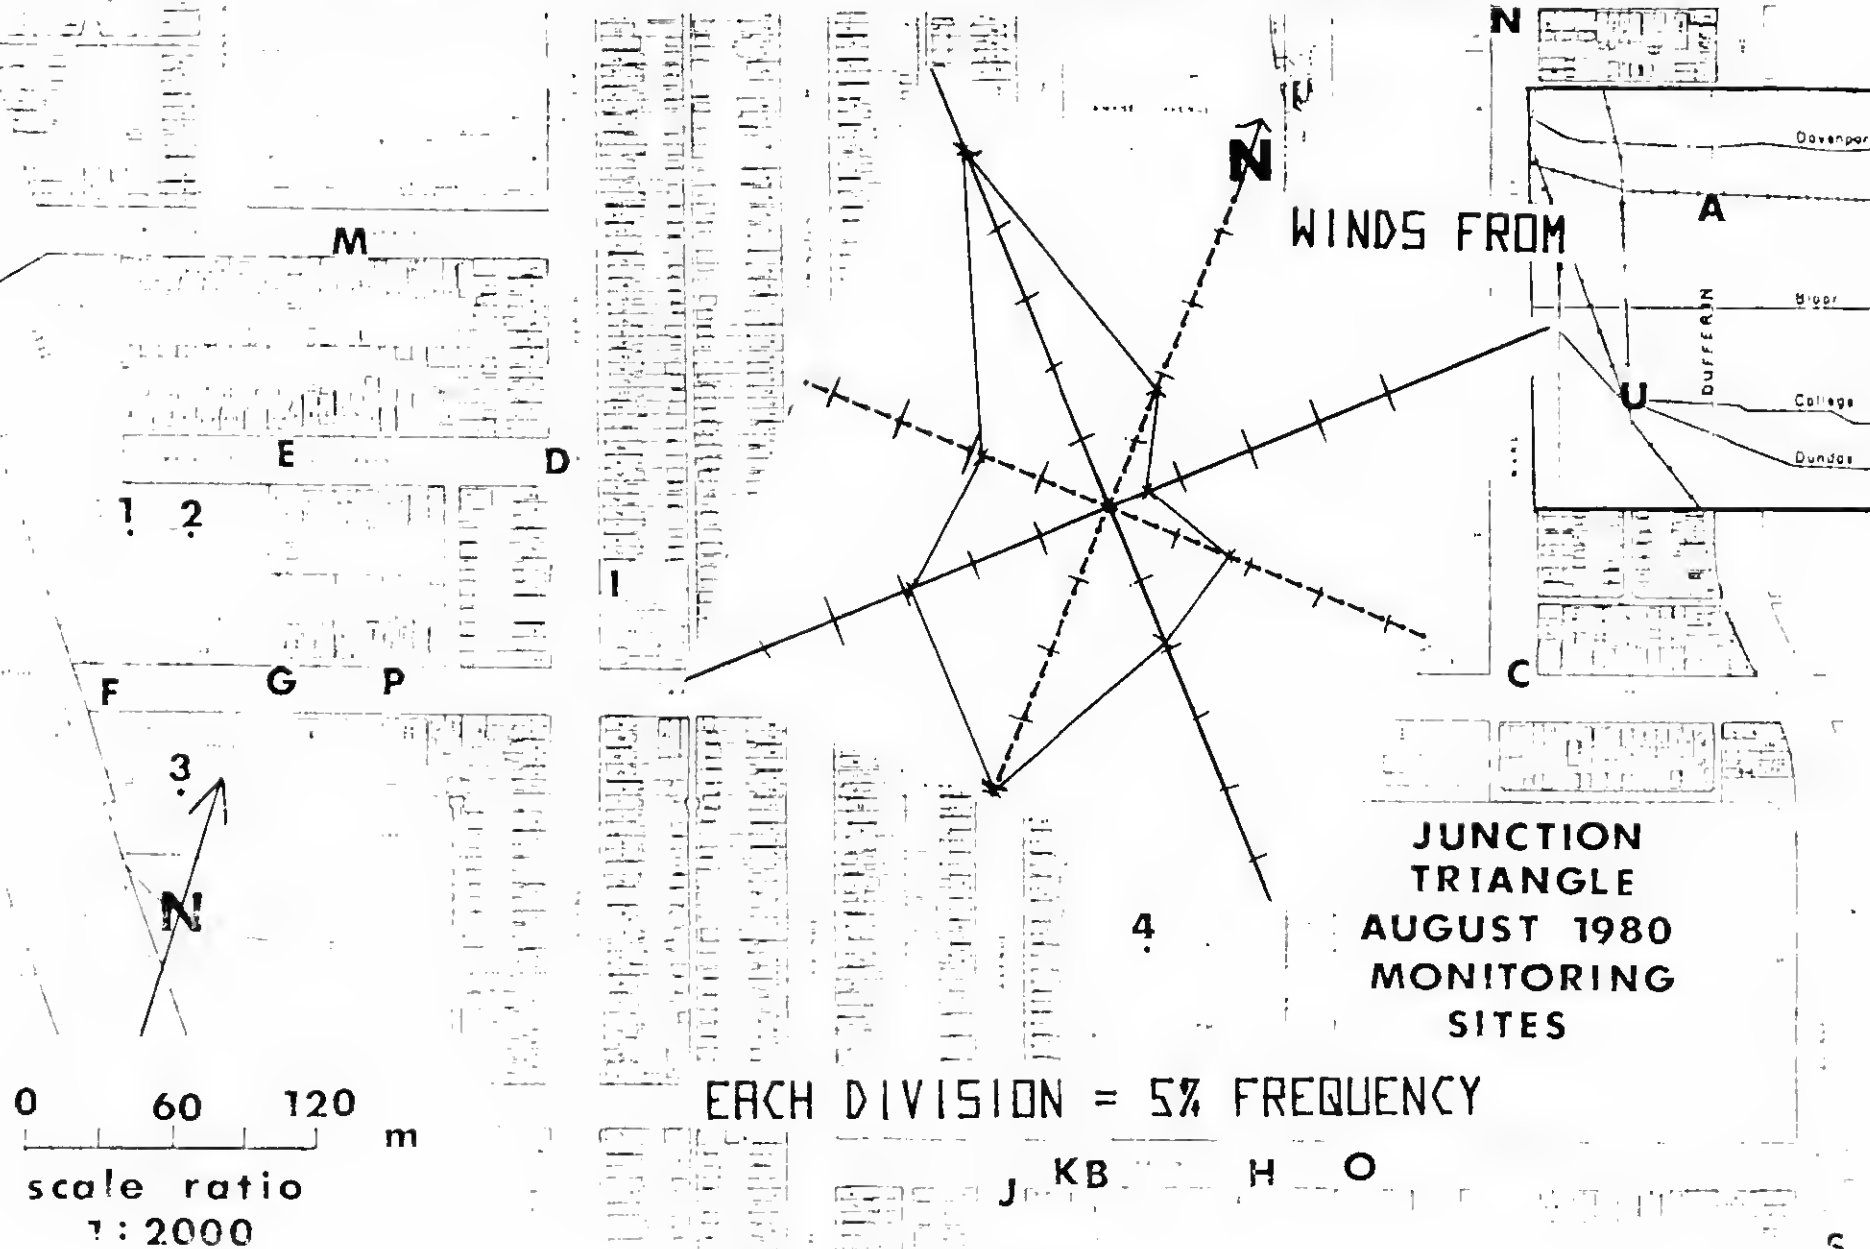

The following Table presents the establish 30-minute Guidelines, as monitored at the point of impingement and as set out by the Ministry of the Environment Regulations for the gaseous hydrocarbon contaminants monitored during this ambient air survey.

TABLE #4

WIND DIRECTION ANALYSES
CONTINUOUS FROM JULY 14 1980 TO AUGUST 4 1980
MET. TOWER LOCATED AT THE TTC BARNES ON PATON ROAD

Total Hydrocarbon - THC

Approximately 54 hours of THC data were acquired during 22 monitoring periods. During this time, the overall average glc of THC was 4.10 ppm with an associated standard deviation 1.20 ppm. The non-methane component (THC-CH₄) showed an overall average glc of 2.64 ppm with an associated standard deviation of 1.02 ppm whereas, the overall average glc of the methane component (CH₄) was relatively low (1.12 ppm) (See statistical summary Tables #10 and 11 on pages 59 to 62.) The above figures suggested that a significant amount of THC was not of a biological origin but was being produced within or transported into the industrial area under investigation.

The maximum one-hour average glc of THC recorded was 7.47 ppm and was acquired on July 24 during monitoring period JUN.TRI #16 (See Graph #5, page 56.) During this time, the MAM unit was located downwind of Glidden as can be seen by the wind rose/concentration analysis Map #3, page 37. (N.B. This wind rose is a 30 minute average representation.)

High values of THC were also recorded downwind of Anchor Cap. During monitoring period JUN.TRI #26, the second highest one-hour average glc of THC was recorded at 6.95 ppm. (See Figure #7 on page 58.) The MAM unit was located adjacent to and downwind of Anchor Cap (See Map #4 on page 42.)

Ozone - O₃

Ozone was monitored during this survey since it is indicative of atmospheric photochemical reactions.

Approximately 54 hours of O₃ data were acquired during 22 monitoring periods. The overall average concentration for the survey period was 0.025 ppm with an associated standard deviation of 0.013 ppm. At no time did the one-hour average glc's of O₃ exceed the Ontario Air Quality Criterion of 0.08 ppm. (The analyzed data is presented in Table #11, pages 61 and 62.)

The highest maximum one-hour average glc recorded was 0.069 ppm and was acquired on July 21 during monitoring period JUN.TRI #5. The MAM unit was located at 30 MaCaulay Street and the winds were light with a northeasterly component. (See Graph #2, on page 53.)

Gas Chromatograph (GC) Analyses

During the survey, a GC unit was set up to monitor specific hydrocarbons. These included methyl ethyl ketone (MEK), benzene, ethyl acrylate, methyl methacrylate, methyl butyl ketone (MBK), toluene, n-octane, ethyl benzene, m-xylene, p-xylene, o-xylene, cyclohexanone, nonane, iso-propyl benzene, 1,3,5 -trimethyl benzene, 1,2,4 - trimethyl benzene, decane and isophorone. The results of the GC analyses are presented in Tables #14 to 17 on pages 69 to 81.

The G.C. analyses are classified according to the monitoring site location; i.e. downwind of Glidden, downwind of Anchor Cap, downwind of Nacan and general air quality of the Junction Triangle area.

From these analyses, it was found that glc's of benzene, ethyl acrylate, methyl methacrylate, n-octane, cyclo hexanone, nonane, iso propyl benzene and n-propyl benzene approached or were at background levels. Only a limited number of

analyses depicted significant glc's of isophorone and decane due to the inability to effectively resolve the chromatogram with respect to these compounds. A summary of the geometric analyses for the remainder of these aforementioned hydrocarbons are presented in Table #5 on page 33.

From this table and a comparison between the geometric mean of the specific hydrocarbon coupled with the general air quality, and the information inferred by the geometric standard deviation, the following general comments were evident. Significant glc's of MEK, toluene, ethyl benzene, total xylenes, 1,3,5-trimethyl benzene and 1,2,4-trimethyl benzene were detected in the vicinity of the Glidden Paint Company. In addition, significant glc's of MBK, nonane, cyclohexanone, 1,3,5-trimethyl benzene and 1,2,4-trimethyl benzene were monitored in the vicinity of Anchor Cap and significant glc's of MEK and toluene were found in the vicinity of Nacan.

NOTE: With respect to the xylenes, the meta (m) and para (p) isomers could not be effectively resolved on the chromatogram. Therefore, the meta concentration results also contain the para contribution. The Criterion and Guidelines for xylenes states total xylenes; i.e. no distinction is made with respect to the 3 xylene isomers.

ND - Not detected

i- Glidden Paint

Sixty-six ambient air samples were acquired in the vicinity of Glidden Paint and the subsequent analyses are summarized in Table #6 on page 38. Using as a benchmark, the concentrations as set out in Table #4 on page 28, only the instantaneous glc's of 1,3,5-trimethyl benzene and 1,2,4-trimethyl benzene were deemed to be significant.

The instantaneous glc results of 1,2,4-trimethyl benzene was the most significant with 7 excursions above 100 ug/m^3 and 21 readings between 50 ug/m^3 to 100 ug/m^3 with the maximum being 231 ug/m^3 .

Relating these instantaneous results to the 30-minute Guideline (benchmark) is very difficult. However during the time period 0559 hours to 0829 hours on July 24th, under light (2-5 km/hr) northwest winds and a slight nocturnal inversion (as indicated by early morning fog and the vertical temperature/wind profile of the atmosphere acquired at 1030 hours - refer to minisonde flight #8 on page 36), 8 discrete samples were acquired and analyzed. The mean glc of 1,2,4-trimethyl benzene from these 8 samples was 146 ug/m^3 (approximately $1\frac{1}{2}$ times the benchmark). Again it must be mentioned that the ambient air sample was injected into the gas chromatograph only when the THC analyzer denoted a definite increase and hence this mean glc for 1,2,4-trimethyl benzene (and other hydrocarbon G.C. analyses) will be weighted towards the higher concentration. As mentioned in the THC discussion, this monitoring period resulted in the highest one-hour average glc of THC reported for the entire survey and its value was 7.47 ppm.

During this same monitoring period, the only excursion above 100 ug/m^3 for 1,3,5-trimethyl benzene was recorded and its instantaneous glc was 109 ug/m^3 .
Only

2 other glc values for 1,3,5-trimethyl benzene were found in the range 50 ug/m^3 to 100 ug/m^3 .

The maxima instantaneous glc's of xylenes (total - 1729 ug/m^3), ethyl benzene (374 ug/m^3), toluene (992 ug/m^3) decane (480 ug/m^3), isophorone (676 ug/m^3) and MEK (513 ug/m^3) also indicated that these hydrocarbons were significant in the vicinity of Glidden.

From these 66 samples, the geometric standard deviation for MEK (2.6), toluene (2.5), ethyl benzene (2.8), xylenes (2.5 to 3) and the trimethyl benzenes (2.8 and 2) strongly suggests that these glc's were originating from the vicinity of Glidden Paint.

Correlation analyses between the instantaneous glc's of toluene and m-xylene acquired in the vicinity of Glidden inferred a mutual origin. For 65 degrees of freedom, the correlation coefficient was found to be 0.25 which is significant at the 95% confidence level.

The maximum instantaneous glc of benzene reported for this area was 70 ug/m^3 and was acquired during the early morning (at 0805 hours) on July 29.

ii- Anchor Cap

Sixty three ambient air samples were acquired in the vicinity of Anchor Cap and the subsequent analyses are summarized in Table #7 on page 43. Again using the premis mentioned in the Glidden discussion, only the instantaneous glc's of 1,3,5-trimethyl benzene and 1,2,4-trimethyl benzene were deemed to be significant.

The instantaneous glc results of 1,2,4-trimethyl benzene were again the most prominant with 21 excursions above of 100 ug/m^3 and 6 glc readings between 50 ug/m^3 and 10 ug/m^3 , with the maximum being 516 ug/m^3 .

Between 1755 hours and 2036 hours on July 17, seven of eight samples analyzed for 1,2,4-trimethyl benzene were greater than 100 ug/m^3 with the maximum being 478 ug/m^3 . The mean glc of 1,2,4-trimethyl benzene for this 2 hour and 40 minute period was 208 ug/m^3 . Two of these eight samples depicted glc's of 1,3,5-trimethyl benzene in excess of 100 ug/m^3 with the maximum being 163 ug/m^3 and one sample contained 152 ug/m^3 of MBK and approximately 380 ug/m^3 of xylenes.

The second monitoring period of elevated concentration results was between 2113 hours and 2239 hours on July 21. Three of the four samples acquired during this 1 1/2 hour period denoted glc's of 1,2,4-trimethyl benzene in excess of 100 ug/m^3 with the maximum being 516 ug/m^3 . The mean glc was 278 ug/m^3 . These four samples had significant glc's of cyclo-hexanone (maximum - 514 ug/m^3 and mean - 291 ug/m^3) and two of the four samples were found to have glc's of nonane in excess of 1000 ug/m^3 with the maximum being 1869 ug/m^3 . Finally, 2 of the 4 samples acquired during this monitoring period depicted glc's of 1,3,5-trimethyl benzene in excess of 100 ug/m^3 with the maximum being 207 ug/m^3 .

On July 23rd between 0743 hours and 0917 hours, 4 consecutive samples were found to have glc's of 1,2,4-trimethyl benzene in excess of 100 ug/m^3 . For this 1½ hour monitoring period, the maximum glc was 139 ug/m^3 and the mean glc was 121 ug/m^3 . For 2 of these 4 samples, glc's of MBK were found to be in excess of 100 ug/m^3 with the maximum being 120 ug/m^3 .

On July 24 between 1918 hours and 2114 hours, 3 of 6 instantaneous samples depicted glc's of 1,2,4-trimethyl benzene in excess of 100 ug/m^3 . The maximum glc of 1,2,4-trimethyl benzene for this 2 hour period was 259 ug/m^3 and the mean of the six samples was 101 ug/m^3 . No other significant glc's for the other hydrocarbons were detected during this monitoring period.

Finally the fifth monitoring period during which excursions above 100 ug/m^3 for 1,2,4-trimethyl benzene were recorded was between 0709 hours and 0918 hours on July 30th. All 7 samples acquired during this 2 hour period exceeded the benchmark of 100 ug/m^3 , with the maximum glc of 1,2,4-trimethyl benzene being 322 ug/m^3 and the mean 227 ug/m^3 . Elevated glc's of 1,3,5-trimethyl benzene were also detected but no results were greater than 95 ug/m^3 . Significant glc's of MBK were detected in all 8 samples collected during this period. The maximum glc of MBK was 289 ug/m^3 and the mean was 195 ug/m^3 .

Again examining the statistical summary table (Table #7 on page 43) for the specific hydrocarbons monitored in the vicinity of Anchor Cap, the geometric standard deviation for MBK (3.0), 1,3,5-trimethyl benzene (4) and 1,2,4-trimethyl benzene (2.5) suggested a discrete source in this area.

Correlation analyses between 1,2,4-trimethyl benzene versus 1,3,5-trimethyl benzene and between 1,2,4-trimethyl benzene versus MBK supports a statement of a mutual source in this area. For 62 degrees of freedom, a correlation coefficient of 0.867 was found between 1,2,4-trimethyl benzene and 1,3,5-trimethyl benzene (deemed highly significant at the 99.9% confidence level) and a correlation coefficient of 0.410 was determined between 1,2,4-trimethyl benzene and MBK (again highly significant at the 99.9% confidence level). These high correlation coefficients were anticipated since the petroleum and coal tar distillates (of which the trimethyl benzenes are major constituents) and MBK were expected to have originated from the same emission point (building #7 at Anchor Cap as referenced in internal memo to C.J. Macfarlane from Kawasaki and Martin on February 21, 1980).

Lower glc's of toluene, xylenes and ethyl benzene were found in the vicinity of Anchor Cap (geometric mean - 36 ug/m^3 , 69 ug/m^3 and 12 ug/m^3 respectively) as compared to the results obtained in the vicinity of Glidden (geometric mean - 150 ug/m^3 , 196 ug/m^3 and 35 ug/m^3 respectively).

The maximum glc of benzene detected in the vicinity of Anchor Cap was 60 ug/m^3 , which is essentially the same as that reported for Glidden.

iii- Nacan

Sixteen ambient air samples were acquired in the vicinity and directly downwind of Nacan and the subsequent analyses are summarized in Table #8 on page 45.

Immediately obvious from this table are the low glc's reported for the various hydrocarbons (with the exception of MEK) and that no instantaneous readings for the specific hydrocarbons were found to be in excess of their respective benchmarks. The maximum glc's reported for 1,3,5-trimethyl benzene and 1,2,4-trimethyl benzene were 33 ug/m^3 and 53 ug/m^3 respectively.

The only significant glc's acquired in the vicinity of Nacan was for toluene and methyl ethyl ketone (MEK). Its maximum glc of toluene was 225 ug/m^3 -approximately the same glc reported for Anchor Cap and $\frac{1}{4}$ the amount reported for Glidden. Seven of the reported 15 MEK glc's comprising this segment of the ambient air survey were greater than 100 ug/m^3 with the maximum glc being 738 ug/m^3 ; the highest reported glc value acquired during this survey.

The maximum glc for total xylenes was 180 ug/m^3 .

The maximum glc for benzene was 85 ug/m^3 .

iv- General

During the last two days of this ambient air survey, the MAM unit was positioned at several locations, apart from the three aforementioned plants, throughout the Junction Triangle. The weather was similar to a regular monitoring day during the past two weeks.

Twenty-one instantaneous samples were acquired at 6 different monitoring sites throughout this area and the results are summarized in Table #9 on page 47.

Low glc's of the various hydrocarbons were detected during this aspect of the survey. The maximum glc of 1,2,4-trimethyl benzene was 41 ug/m^3 and for 1,3,5-trimethyl benzene 16 ug/m^3 . The maximum glc's for total xylenes was 142 ug/m^3 , for toluene 153 ug/m^3 and for benzene 92 ug/m^3 . This glc value for benzene was the highest reported during this survey but at the time of monitoring, the MAM unit was located downwind of a gas station located at Dundas and College Streets.

[illegible]

v- Comments

- A. In general the maximum glc's for the various hydrocarbons were detected during the early morning hours under calm meteorological conditions (induced by subsidence or nocturnal cooling) or at night after 2100 hours EST under similar conditions.
- B. Source delineation especially between Nacan and Glidden was very critical during this survey due to the close proximity of these two plants and the realization that most of the monitoring was conducted along McCauley Street. Great care and attention was taken by the field operators so as to ensure that the acquired data (instantaneous sampling) was taken from locations indicative of only one source. This sometimes meant using a sampling hose connected to the sample probe on the MAM unit for more directional acquisition of the ambient air sample.
- C. Humid, hot and unstable meteorological conditions generally persisted throughout the daytime monitoring periods comprising this survey.
- D. The main aim of this survey was to acquire maximum glc values for the specific hydrocarbons.
- E. A number of odour complaints were received and responded to by the MAM personnel. However by the time the call was received, often

several hours had lapsed between the time the call was taken by the Central Region office and the time it was received by the MAM unit. Needless to say, when the MAM personnel responded, the odour had dissipated in the area of concern.
